# Congressional Apportionment 

David Housman<br>Mathematics and Computing<br>Goshen College

March 27, 2021

## The Constitutional Basis

"Representatives and direct Taxes shall be apportioned among the several States which may be included within this Union, according to their respective Numbers . . . . The actual Enumeration shall be made within three years after the first meeting of the Congress of the United States, and within every subsequent Term of ten Years, in such manner as they shall by Law direct."
article I, section 2

## What is the Problem?

Consider populations from the 1990 census ...

$$
\begin{aligned}
& \text { quota }_{\mathrm{CA}}=\frac{\text { population of CA }}{\text { population of USA }} \times \text { house size }=\frac{33,930,798}{281,434,177} \times 435=52.447 \\
& \text { quota }_{\mathrm{UT}}=\frac{\text { population of UT }}{\text { population of USA }} \times \text { house size }=\frac{2,236,714}{281,434,177} \times 435=3.457
\end{aligned}
$$

The official apportionment was
apportionment $_{\text {CA }}=53$
apportionment $_{U T}=3$

## United States of Arithmetic

| State | Population | Quota | Apportionment |
| :---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ |
| Add | 9,598 | 47.99 |  |
| Sub | 5,868 | 29.34 |  |
| Mul | 2,664 | 13.32 |  |
| Div | 1,870 | 9.35 |  |
| Total | 20,000 | 100.00 | 100 |

- Simple rounding does not work.
- If we start by rounding down, how should we distribute the two remaining seats?
- In order of populations $p_{i}$ (ascending or descending)?
- In order of remainders $r_{i}=q_{i}-\left\lfloor q_{i}\right\rfloor$ (ascending or descending)?
- In order of relative remainders $r_{i} / p_{i}$ (ascending or descending)?

## Hamilton's Method

Give to each state the whole number contained in its quota, and then assign remaining seats to states with the largest quota remainders.

| State | Population | Quota | Apportionment |
| :---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ |
| Add | 9,598 | 47.99 | $47+1=48$ |
| Sub | 5,868 | 29.34 | $29+0=29$ |
| Mul | 2,664 | 13.32 | $13+0=13$ |
| Div | 1,870 | 9.35 | $9+1=10$ |
| Total | 20,000 | 100.00 | 100 |

## Jefferson's Method

Choose an ideal district size. Compute the ratios of population to the ideal district size. Give each state the whole number in its ratio seats. If the house size is fixed, the ideal district size must be chosen so that the seats assigned matches the house size.

| State | Population | Ratio | Apportionment |
| :---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $p_{i} / 200$ | $a_{i}$ |
| Add | 9,598 | 47.99 | 47 |
| Sub | 5,868 | 29.34 | 29 |
| Mul | 2,664 | 13.32 | 13 |
| Div | 1,870 | 9.35 | 9 |
| Total | 20,000 |  | 98 |

## Jefferson's Method

Choose an ideal district size. Compute the ratios of population to the ideal district size. Give each state the whole number in its ratio seats. If the house size is fixed, the ideal district size must be chosen so that the seats assigned matches the house size.

| State | Population | Ratio | Apportionment |
| :---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $p_{i} / 195.7$ | $a_{i}$ |
| Add | 9,598 | 49.04 | 49 |
| Sub | 5,868 | 29.98 | 29 |
| Mul | 2,664 | 13.61 | 13 |
| Div | 1,870 | 9.56 | 9 |
| Total | 20,000 |  | 100 |

## Webster's Method

Choose an ideal district size. Compute the ratios of population to the ideal district size. Give each state its rounded ratio seats. If the house size is fixed, the ideal district size must be chosen so that the seats assigned matches the house size.

| State | Population | Ratio | Apportionment |
| :---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $p_{i} / 198$ | $a_{i}$ |
| Add | 9,598 | 48.47 | 48 |
| Sub | 5,868 | 29.63 | 30 |
| Mul | 2,664 | 13.45 | 13 |
| Div | 1,870 | 9.44 | 9 |
| Total | 20,000 |  | 100 |

## Hill's Method

Choose the apportionment that minimizes the relative difference in average representation between pairs of states.

| State | Population | Quota |  |  | Apportionments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ | $a_{i}$ |  |
| Sub | 5,868 | 29.58 | 29 | 30 |  |
| Div | 1,870 | 9.42 | 10 | 9 |  |
| Total | 7,738 | 39.00 | 39 | 39 |  |
|  | Pairwise |  | $\frac{10}{1870}-\frac{29}{5868}$ | $=0.0758$ | $\frac{\frac{30}{5868}-\frac{9}{1870}}{30}=0.0586$ |
|  | Measure |  | $\frac{10}{1870}$ | $\frac{30}{5868}$ |  |

For our example, Hill's and Webster's methods yield the same apportionment. For some distributions of population, the two methods give different results.

## Divisor Methods

Choose an ideal district size $\lambda$.
State $i$ receives $p_{i} / \lambda$ rounded with OR respect to a divisor criterion seats.

Choose an apportionment that minimizes a pairwise measure of inequity.

| Method | Divisor | Inequity Measure |
| :--- | :---: | :---: |
| Jefferson | $a+1$ | $a_{i}\left(p_{j} / p_{i}\right)-a_{j}$ |
| Webster | $a+1 / 2$ | $a_{a} / p_{i}-a_{j} / p_{j}$ |
| Hill | $\sqrt{a(a+1)}$ | $\frac{a_{i} / p_{i}}{a_{j} / p_{j}}-1$ |
| Dean | $\frac{a(a+a)}{a+1 / 2}$ | $p_{j} / a_{j}-p_{i} / a_{i}$ |
| Adams | $a$ | $a_{i}-a_{j}\left(p_{i} / p_{j}\right)$ |

## Does it Make a Real Difference?

| For the 1990 Census |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
| State | Quota | Hamilton | Webster | Hill |
| Massachusetts | 10.552 | 11 | 11 | 10 |
| Oklahoma | 5.516 | 5 | 5 | 6 |
| New Jersey | 13.536 | 14 | 13 | 13 |
| Mississippi | 4.518 | 4 | 5 | 5 |

Jefferson would have changed 16 state apportionments.

## For the 2000 Census

Webster is the same as Hill. Hamilton takes a seat from California and gives it to Utah. Jefferson adds two seats to California among several other changes.

For the 2010 Census
Hamilton is the same as Hill. Webster takes a seat from Rhode Island and gives it to North Carolina. Jefferson adds two seats to California among several other changes.

## What Method is Best?

"Since the world began there has been but one way of proportioning numbers, namely,
[insert your favorite method here]
nor can there be any other method. This process is purely arithmetical,... If a hundred men were being torn limb from limb, or a thousand babes were being crushed, this process would have no more feeling in the matter than would an iceberg; because the science of mathematics has no more bowels of mercy than has a cast-iron dog."

Representative John A. Anderson of Kansas
Congressional Record 1882, 12:1179

## What Method is Best?

- Method definitions are ad hoc.
- Webster was used seven times (1840, 1850, 1880, 1890, 1900, 1910, and 1930); Jefferson was used five times (1790 through 1830); Hill was used eight times (1940 through 2010). Twice (1860 and 1870) no consistent method was used; and once (1920) there was no reapportionment.
- Edward V. Huntington (The Apportionment of Representatives in Congress, Transactions of the American Mathematical Society, 1928) made the first systematic study of methods based upon measures of inequity..
- Michel L. Balinski and H. Peyton Young (Fair Representation: Meeting the Ideal of One Man, One Vote, 1982) use an axiomatic approach based upon desirable properties.

## Fair Share

The number of seats assigned a state should be its quota rounded down or up.

| State | Population | Quota | Jefferson <br> $i$ |
| :---: | ---: | ---: | ---: |
| $p_{i}$ | $q_{i}$ | $a_{i}$ |  |
| Add | 9,598 | 47.99 | 49 |
| Sub | 5,868 | 29.34 | 29 |
| Mul | 2,664 | 13.32 | 13 |
| Div | 1,870 | 9.35 | 9 |
| Total | 20,000 |  | 100 |

- Jefferson's method does not satisfy fair share (consider Add in USA).
- No divisor method satisfies fair share.
- Hamilton's method satisfies fair share.

## House Monotonicity

No state loses a seat when the house size increases (populations unchanged).

| State | 100 seats |  | 100 seats |  |
| :---: | ---: | ---: | ---: | ---: |
| $i$ | $q_{i}$ | $a_{i}$ | $q_{i}$ | $a_{i}$ |
| Add | 47.99 | 48 | 48.47 | 49 |
| Sub | 29.34 | 29 | 29.63 | 30 |
| Mul | 13.32 | 13 | 13.45 | 13 |
| Div | 9.35 | 10 | 9.44 | 9 |
| Total | 100.00 | 100 | 101.00 | 101 |

- Hamilton's method does not satisfy house monotonicity (consider Div in USA).
- All divisor methods satisfy house monotonicity.
- There are methods satisfying both fair share and house monotonicity.

## Population Monotonicity

No state that increases its population should lose a seat to another state that decreases its population (house size unchanged).

| State | First Census |  | Second Census |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ | $p_{i}$ | $q_{i}$ | $a_{i}$ |
| Add | 9,598 | 47.99 | 48 | 9,550 | 47.99 | 48 |
| Sub | 5,868 | 29.34 | 29 | 5,865 | 29.47 | 30 |
| Mul | 2,664 | 13.32 | 13 | 2,610 | 13.12 | 13 |
| Div | 1,870 | 9.35 | 10 | 1,875 | 9.42 | 9 |
| Total | 20,000 | 100.00 | 100 | 19,900 | 100.00 | 100 |

- Hamilton's method does not satisfy population monotonicity (consider Div and Sub of USA).
- All divisor methods satisfy population monotonicity.
- There is no method satisfying both fair share and population monotonicity.
- Would weaker forms of these properties or other properties characterize methods?

## Relative Population Monotonicity

No state that increases its relative population should lose a seat to another state that decreases its relative population (house size unchanged).

| State | First Census |  |  | Second Census |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ | $p_{i}$ | $q_{i}$ | $a_{i}$ |
| Add | 9,598 | 47.99 | 48 | 9,550 | 47.99 | 48 |
| Sub | 5,868 | 29.34 | 29 | 5,865 | 29.47 | 30 |
| Mul | 2,664 | 13.32 | 13 | 2,610 | 13.12 | 13 |
| Div | 1,870 | 9.35 | 10 | 1,875 | 9.42 | 9 |
| Total | 20,000 | 100.00 | 100 | 19,900 | 100.00 | 100 |

- Hamilton's method does satisfy relative population monotonicity (notice that Div and Sub both increase their relative populations as can be seen in their quotas).
- Since population monotonicity implies relative population monotonicity, all divisor methods satisfy population monotonicity.

## Near Fair Share

The transfer of a seat from one state to another does not simultaneously take both states closer to their quota.

| State | Population | Quota | First | Second |
| :---: | ---: | ---: | ---: | ---: |
| $i$ | $p_{i}$ | $q_{i}$ | $a_{i}$ | $a_{i}$ |
| Add | 9,598 | 47.99 | 47 | 48 |
| Sub | 5,868 | 29.34 | 30 | 29 |
| Mul | 2,664 | 13.32 | 13 | 13 |
| Div | 1,870 | 9.35 | 10 | 10 |
| Total | 20,000 | 100.00 | 100 | 100 |

- The example shows that the first apportionment is not fair share.
- Hamilton's method satisfies near fair share.
- Websters's method is the unique method satisfying near fair share and population monotonicity.
- Although sounding related, near fair share is independent of fair share.

## Unbiased

The probability that state $i$ is favored over state $j\left(a_{i} / p_{i}>a_{j} / p_{j}\right)$ equals the probability that state $j$ is favored over state $i\left(a_{j} / p_{j}>a_{i} / p_{i}\right)$.

| Quota | Jefferson | Webster | Hill | Dean | Adams |
| :---: | ---: | ---: | ---: | ---: | ---: |
| 9.988 | $\mathbf{1 1}$ | 10 | 10 | 10 | 10 |
| 9.064 | 9 | 9 | 9 | 9 | 9 |
| 7.182 | 7 | $\mathbf{8}$ | 7 | 7 | 7 |
| 5.260 | 5 | 5 | $\mathbf{6}$ | 5 | 5 |
| 3.321 | 3 | 3 | 3 | $\mathbf{4}$ | 3 |
| 1.185 | 1 | 1 | 1 | 1 | $\mathbf{2}$ |

- There is a clear ordering in the five traditional divisor methods from bias towards large states (Jefferson) and bias towards small states (Adams).
- Under a variety of reasonable assumptions about the population probability distribution, Hamilton's method is unbiased and Webster's method is the unique unbiased and proportional divisor method.

## Summary

| Property | Hamilton | Webster | Hill | Jefferson |
| :--- | :---: | :---: | :---: | :---: |
| Fair Share | Yes | No | No | No |
| Near Fair Share | Yes | Yes | No | No |
| Unbiased | Yes | Yes | No | No |
| Population Monotone | No | Yes | Yes | Yes |
| Relative Population Monotone | Yes | Yes | Yes | Yes |
| House Monotone | No | Yes | Yes | Yes |

## Conclusions

- Webster's or Hamilton's method would be an improvement upon Hill's method.
- Can Hamiliton's method be characterized with fair share, unbiased, and relative population monotonicity?
